

Hi _____,

As discussed, here is a real-world challenge. This is exactly what you will be doing if you join our team.

Deliverables:

- Assume you are the QA engineer in-charge of testing the **College Finder module** on <https://yocket.com/>
- You have to create a web automation test for **College Finder** for all the steps. On the first screen, select "Masters". On the screens that follow all mandatory fields must be filled with valid data and the list of colleges should be displayed. From this list, sort by price and shortlist the first university.
- You may use any tool you are comfortable with (Selenium Web driver, TestNG etc)
- The test should cover all scenarios, including edge cases.
- You may upload your project to a git repo and share the link with us
- Please include a README file that explains what you have done, and your thought process
- We will contact you and schedule a short call for you to walk us through the automation with a demo and explain your code.

Feel free to contact us or respond to this email with any questions or clarifications.
